But the result is a warning: warning: ISO C++ says that 'int x = FOO;' is ambiguous, could be 'int x = 8;'. And if I put an extern in file.h, there is no warning. #define FOO 8 #include "file.h" int main(void) { extern int x = FOO; // global variable with extern printf("%d ", x); // What can I expect as a result? } It is clear that in file.h, there is no global variable of x so #define FOO 8 did not make #include file.h change x. But why does it happen in c99? Are there other reasons? A: Since you're using the preprocessor, the definition of the variable x is not part of the translation unit (source code file) being compiled. That's why the compiler can't figure out which definition to use. By using the extern keyword, you're telling the compiler that, for all intents and purposes, the variable x is already defined in another translation unit. 1. Field of the f678ea9f9e
